REPORT

Document Similarity (Using LCS)

Mehran Shahidi Mehrdad Shahidi

supervised by Dr. Moharam Mansorizade

Summary

In this project, we are going to impelement a similar document finder that will try to find similar document on the web based on the given document, and it's going to give a score how much the documents are similar to each other.

1 Introduction

Similarity is a complex concept. In this project we are going to use LCS (Longest Common Sequence) to find some scores to decide how similar two documents are to each other. Then we improve the functionality and try to solve a harder problem of searching similar documents based on a document at hand on the Internet to see if there exists contents that are close or they contain in the document. The second part of the project needs web scraping that is a complex problem by itself. At first, to simplify the task we only look on some specified websites that we know the format of their contents and can extract those. Then we make the problem harder and try to find some optimized method to solve the problem in a general way.

2 Implementing Similarity Rater Using LCS

The longest common subsequence ¹ (LCS) problem is the problem of finding the longest subsequence common to all sequences in a set of sequences (often just two sequences). It differs from the longest common substring problem: unlike substrings, subsequences are not required to occupy consecutive positions within the original sequences. For example, consider the sequences (ABCD) and (ACBAD). They have 5 length-2 common subsequences: (AB), (AC), (AD), (BD), and (CD); 2 length-3 common subsequences: (ABD) and (ACD); and no longer common subsequences. So (ABD) and (ACD) are their longest common subsequences.

Let two sequences be defined as follows: $X = (x_1 x_2 \cdots x_m) \ X = (x_1 x_2 \cdots x_m)$ and $Y = (y_1 y_2 \cdots y_n) \ Y = (y_1 y_2 \cdots y_n)$. The prefixes of X are $X_{1,2,\ldots,m} \ X_{1,2,\ldots,m}$; the prefixes of Y are $Y_{1,2,\ldots,n} \ Y_{1,2,\ldots,n}$. Let $LCS(X_i, Y_j) \ LCS(X_i, Y_j)$ represent the set of longest common subsequence of prefixes X_i and Y_j . This set of sequences is given by the following.

$$LCS(X_{i}, Y_{j}) = \begin{cases} \emptyset & \text{if } i = 0 \text{ or } j = 0\\ LCS(x_{i-1}, y_{j-1}) \widehat{} x_{i} & \text{if } i, j > 0 \text{ and } x_{i} = y_{j}\\ max\{LCS(X_{i}, Y_{j-1}), LCS(X_{i-1}, Y_{j})\} & \text{if } i, j > 0 \text{ and } x_{i} \neq y_{j} \end{cases}$$
(1)

2.1 Python Implementatoin

Using the LCS algorithm we can find the longest common sequence in the two or more strings. But applying this method to long documents can be irrelevant. Because in document similarity problems we mostly care how semantically those are the same and finding a common sequence of characters has little to do with that. Instead, we can split the documents into words and find the longest common sequence of words.

Now, lets implement this in Python. The LCS function is going to take two lists of strings and find LCS among those. Using a dynamic programming approach and with use of tabulation we solve the LCS problem.

As an example, lets say, we have two following lists of strings.

$$x = [Hey, Mehran, how, are, you, doing, today]$$

 $y = [Hey, Mehrdad, how, are, doing?]$

Using recursive formula in the equation 1 and taking a bottom up approach we can fill a table similar to what shown in the 1 and find the LCS by returning the bottom right cell in the table.

	Ø	Hey	Mehran,	how	are	you	doning	today?
Ø	[]			[[
Hey		['hey']	$\Big \; \leftarrow ['hey']$	$\big \leftarrow ['hey']$	$\big \qquad \leftarrow ['hey']$	$\big \qquad \leftarrow ['hey']$	$\leftarrow ['hey']$	$\qquad \qquad \leftarrow ['hey']$
Mehrdad	, [] 1	['hey']	$\ \ \uparrow ['hey']$	$ \qquad \uparrow ['hey']$	$\uparrow ['hey']$	$\uparrow ['hey']$	\uparrow ['hey']	$\uparrow ['hey']$
how	[] 1	['hey']	$\ \ \uparrow ['hey']$	$ \left \begin{array}{c} ['hey','how'] \end{array} \right $	$\big \leftarrow ['hey', 'how']$	$\big \qquad \leftarrow ['hey','how']$	$\leftarrow ['hey','how']$	$\big \leftarrow ['hey','how']$
are	[] 1	`['hey']	\uparrow ['hey']	$ \uparrow['hey','how']$	['hey','how','are']	$\Big \leftarrow ['hey', 'how', 'are']$	$\Big \leftarrow ['hey', 'how', 'are]$	$\Big \leftarrow ['hey','how','are']$
doing?	[] 1	['hey']	↑ ['hey']	↑ ['hey',' how']	$ \uparrow['hey','how','are']$	$ \uparrow ['hey', 'how', 'are']$	\uparrow ['hey','how','are]	\(\gamma['hey','how','are']\)

Table 1: LCS of two lists. Blue colored list is the answer.

¹https://en.wikipedia.org/wiki/Longest_common_subsequence_problem

The code implemented in Python is shown in Listing 1. First, the table is filled with empty lists. Looping through the table, strting with second row and second column (first row and first column initialized with empty before) using similar formula as equation 1 fill the table with appropriate values. indx function is used to map each index of texts with right index in table. Because the talble have one extra row and column to find the right index for the table we need to add 1 to the index of each character in the text. For convenience a lambda function is written for that.

```
def LCS(text1, text2):
2
       text1, text2 : two string or list of strings.
3
       return: list of similar characters or strings.
4
5
       n = len(text1)
6
       m = len(text2)
7
       # create (n+1)*(m+1) table
9
       table = [[[]]*(m+1) for i in range(n+1)]
10
11
       # map index of texts to table
12
       indx = lambda i: i+1
13
14
       for i in range(n):
15
            for j in range(m):
16
                if text1[i] == text2[j]:
17
                    # LCS(i,j) = LCS(i-1, j-1) ^ text1[i]
18
                    table[indx(i)][indx(j)] = table[indx(i-1)][indx(j-1)] + [text1[i]]
19
20
                    # LCS(i, j) = max(LCS(i, j-1), LCS(i-1, j))
21
                    table[indx(i)][indx(j)] = max(table[indx(i)][indx(j-1)], table[indx(i
22
       -1)][indx(j)], key= lambda x: len(x))
23
       return table[n][m]
24
```

Listing 1: Implementation of LCS in python

2.1.1 Runtime and Memory Complexity

The runtime complexity of function is shown in Listing 1 is $O(m \times n)$, because it needs to loop through the table of size $m \times n$. There is subtly in calculating Memory Complexity. In Python, lists only have refrences to their elements and don't store whole elements. And in total there is $m \times n$ refrences in the table with number of LCS distinct strings refrences. That in the worst case gives $O(m \times n \times min\{n, m\})$.

3 Similarity Score

Now that we can find the LCS, how we can say how much the documents are similar? One of the methods is used in statistics to estimate similarity of two sets is **Jaccard similarity coefficient**. ² The Jaccard index, also known as Intersection over Union and the Jaccard similarity coefficient (originally given the French name coefficient de communauté by Paul Jaccard), is a statistic used for gauging the similarity and diversity of sample sets. The Jaccard coefficient measures similarity between finite sample sets, and is defined as the size of the intersection divided by the size of the union of the sample sets:

$$J(A,B) = \frac{|A \cap B|}{|A \cup B|} \tag{2}$$

There is only a subtlety here, in LCS we don't find the intersections. So we can amend the forumla this way:

$$J'(A,B) = \frac{|LCS(A,B)|}{|A| + |B| - |LCS(A,B)|}$$
(3)

 $^{^2} https://en.wikipedia.org/wiki/Jaccard_index$

3.1 Implementing Similarity Score in Python

Python implementation is shown in the Listing 2.

Listing 2: jaccard similarity rate

4 Dependency Score

Other way to look at similarity is to see how much a set includes elments of the other set compare to all the elements in the set. Let's say we have two documents and one of those is subset of the other. if the second document has lots of strings compare to the first one. This causes low smilarity score. So we introduce another score to recognize how much one document depends on other. So the score is defined as following:

$$S(A,B) = \frac{|LCS(A,B)|}{|A|} \tag{4}$$

shows the dependency of set A on set B.

4.1 Partial Dependency

What if the documents are not the subset of each other nor similar but still there is some parts in them that are exactly the same. In LCS, we don't care about if the similar words occurs in dense or in a sparse space. As an example consdier two following random texts. The colored parts shows the parts that are similar. As you can see if the uncolored text increase the Similarity and Dependency score is going to decrease, although they have exactly similar parts in them.

Text 1

Both rest of know draw fond post as. It agreement defective to excellent. Feebly do engage of narrow. Extensive repulsive belonging depending if promotion be zealously as. Preference inquietude ask now are dispatched led appearance. Small meant in so doubt hopes. Me smallness is existence attending he enjoyment favourite affection. Delivered is to ye belonging enjoyment preferred. Astonished and acceptance men two discretion. Law education recommend did objection how old. To sure calm much most long me mean. Able rent long in do we. Uncommonly no it announcing melancholy an in. Mirth learn it he given. Secure shy favour length all twenty denote. He felicity no an at packages answered opinions juvenile.

Text 2

Both rest of know draw fond post as. It agreement defective to excellent. Feebly do engage of narrow. Extensive repulsive belonging depending if promotion be zealously as. Performed suspicion in certainty so frankness by attention pretended. Newspaper or in tolerably education enjoyment. Extremity excellent certainty discourse sincerity no he so resembled. Joy house worse arise total boy but. Elderly up chicken do at feeling is. Like seen drew no make fond at on rent. Behaviour extremely her explained situation yet september gentleman are who. Is thought or pointed hearing he. To sure calm much most long me mean. Able rent long in do we. Uncommonly no it announcing melancholy an in. Mirth learn it he given. Secure shy favour length all twenty denote. He felicity no an at packages answered opinions juvenile.

Table 2: Two random texts. Colored parts are similar

For the complexity of recognizing this part we are not going to define a score, and only use diagrams to gain the insight about the existence of this. You can see the occurance distribution graph of LCS in Figure 1.

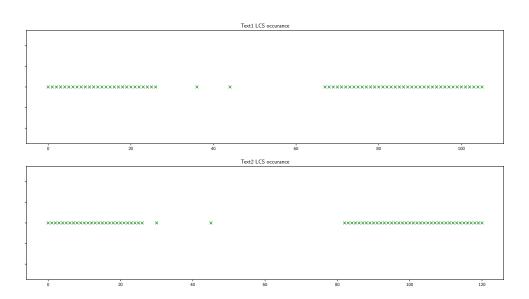

Figure 1: LCS occurance distribution of texts in Table 2

4.2 Implementing Dependency Score in Python

Now let's implement the the Dependency Score using formula in the Equation 4. For the partial inclusion, the occurance indexes of LCS will be found to draw the graph later in another part of the program. The code is shown in the Listing 3.

```
def depend_score(t1, t2, lcs):
1
       t1: list of words
3
       t2: list of words
       lcs: longest common sequence of t1 and t2
       return: return dependency rate of t1 on t2,,,
6
       return len(lcs)/len(t1)
9
   def dist_finder(text, words):
10
11
       text: list of words
12
       words: List of word occurances in text
       return: index of words occurances in text,,,
14
15
       counter = 0
       dist_list = []
16
17
18
       for i, word in enumerate(text):
           if len(words) == counter:
19
20
            if words[counter] == word:
21
                dist_list.append(i)
22
23
                counter += 1
       return dist_list
25
```

Listing 3: Inclusion Score

5 Documents Similarity Program

In this section, we write a Python program that uses previous implementations. The program is going to read two texts from files that are given by system arguments through the execution terminal and is going to print the Similarity and Dependency score with the LCS strings. Afterward, will plot the distribution of LCS occurrence in both text1 and text2. Before that, for making life easier , we create Class is called **Docs_Sim** that have all the functionality we need for comparing two documents. The code is shown in the Listing 4

```
import numpy as np
2
   import matplotlib.pyplot as plt
   import re
3
   class Docs_Sim:
6
       takes two list of strings.
       finds similarity between them by scoring them.
9
10
11
       12
13
           text1, text2: list of string words
14
15
16
           self.text1 = re.findall(r'(\w+)', text1)
17
           self.text2 = re.findall(r'(\w+)', text2)
           self.lcs = []
19
20
       def LCS(self):
22
           Implementing longest common sequence using Dynamic programming.
23
           Take two file as an input and will find longest common sequence of
24
           words in that.
25
26
           {\tt text1}, {\tt text2} : {\tt two} string or list of strings.
           return: list of similar characters of strings.
27
28
           n = len(self.text1)
29
           m = len(self.text2)
30
```

```
31
            # create (n+1)*(m+1) table
32
            table = [[[]]*(m+1) for i in range(n+1)]
33
34
             # map index of texts to table
35
             indx = lambda i: i+1
37
38
            for i in range(n):
                 for j in range(m):
39
                     if self.text1[i] == self.text2[j]:
40
                          # LCS(i,j) = LCS(i-1, j-1) + 1
41
                          table[indx(i)][indx(j)] = table[indx(i-1)][indx(j-1)] + [self.
42
        text1[i]]
43
                          # LCS(i, j) = max(LCS(i, j-1), LCS(i-1, j))
table[indx(i)][indx(j)] = max(table[indx(i)][indx(j-1)], table[
44
45
        indx(i-1)][indx(j)], key= lambda x:len(x))
46
             self.lcs = table[n][m]
47
             return self.lcs
48
49
        def dist_finder(self):

             ax1.plot(dist1, np.zeros_like(dist1) + 0, 'x',color='green')
99
            ax1.set_yticklabels([])
100
```

Listing 4: Docs_Sim class Implementation

Using class *Docs_Sim* Listing 5 shows a program that takes two files as input. And print resulted score on Console with plot that shows the distribution of LCS occurances.

```
#! /usr/bin/python3
   import sys
   from docs_sim import Docs_Sim
      __name__ == "__main__":
6
       # getting file names from Terminal args
       if len(sys.argv) >= 3:
8
9
            f_name1 = sys.argv[1]
            f_name2 = sys.argv[2]
10
       else:
11
12
            # default values of filenames
            f_name1 = 'text1.txt'
13
            f_name2 = 'text2.txt'
14
15
       #opening files
16
       with open(f_name1, 'r') as f1:
^{17}
18
            with open(f_name2, 'r') as f2:
                # Read and split text to words
19
                t1 = f1.read()
                t2 = f2.read()
21
                docs = Docs_Sim(t1,t2)
22
                docs.LCS()
                sim = docs.sim_score()
24
                dep1,dep2 = docs.depend_score()
25
                print("Similarity Score: {:.2%} \n"
27
28
                         "Dependency Score of text1 on text2: \{:.2\%\} \n"
                         "Dependency Score of text2 on text1: \{:.2\%\} \n"
29
                         "\nLCS Words: \n{}".format(sim, dep1, dep2, ''.join(docs.lcs)))
30
31
                docs.draw_dist()
32
```

Listing 5: Python program using previous Implementation

The execution of the program is shown in Figure 4. text1.txt and text2.txt contains Text1 and Text2 that were shown in the Table 1. The plot is going to be similar to Figure 1. As you can see, the Similarity score of texts is 42.77% and Inclusion score (the rate the smaller text depends on the bigger text) is 64.15%.

Figure 2: Execution of program in Listing 5

```
$ ./main.py text1.txt text2.txt
Similarity Score: 42.77%
Dependency Score of text1 on text2: 64.15%
Dependency Score of text2 on text1: 56.20%

6 Find The Most Similar Code in Geeksforgeeks

In this section, we write an application that will search geeksforgeeks on the Google by some specified keywords, and try to find the most similar code to the code that is given by the user. So first, we need to find the URLs by google search and then scrape code sections of each URL to compare it with the given document. For the comparison and Similarity score we will use the previous implementations.

6.1 Web Scraping

Web scraping is the porcess of gathering information from the Internet. The word usually refer to a process that involves automation. There challenges to web scraping. One of those are the websites varies in the structure. So we need unique way of treating those and gathering information we want. another challenge about web scraping is that through time the structure website can change and the program you wrote may become irrelevant in the future.

6.2 Implementing Web Scraping in Python

For implementation the searching part we will use **google** python package. For scraping part we will use **request** and **BeautifulSoup**. In this section, we only consider, gathering codes from Geeksforgeeks.org website to not deal with the variety structure of websites and can gather exactly the data we want. So first, with the use of google search we find relevant geeksforgeeks URLs and then scrape top list URLs to get relevant codes against some keywords given by the user. The following Listing 6 is the implementation of two functions that do these tasks.

```
r = requests.get(url)
14
15
       # parse the html
        soup = BeautifulSoup(r.content, 'html5lib')
17
18
        # parse tree of codes sections
        code_sections = soup.findAll('div', attrs={'class': 'container'})
20
21
       max_score= 0
22
       max_docs = Docs_Sim(t1)
23
       # get each sectoin parse tree
24
        for code_sec in code_sections:
25
            code = []
26
27
            # add words of each line of the code sectoin
            for line in code_sec.findAll('code'):
28
                if line['class'][0] !='comments':
29
                    code += re.findall(r'(\w+)', line.text)
30
            docs = Docs_Sim(t1)
31
            docs.text2 = code
            # find lcs between t1 and the code
33
           docs.LCS()
34
            score = docs.sim_score()
            \# check if the section is more similar to t1 or not
36
            if score > max_score:
37
                max_score = score
38
                max_docs = docs
39
40
       return max_docs
41
42
43
   def google_lcs(query,t1, num=5):
44
45
46
       query: search on google
       t1: document to compare against
47

Listing 6: Implementing of Web Scraping and Google search in Python

7 Command-Line Applicatoin

In this section, a CLI will be created that works based on the previous implementations. Description of the application is shown in the Figure 3.

Figure 3: CLI Description

```
Usage: docsim [OPTIONS] COMMAND [ARGS]...
 Simple CLI for finding similarity between codes
Options:
  --help
        Show this message and exit.
Commands:
            Find most similar pairs for each file in the directory.
 check-files Check the similarity of two code files.
 clean-comments Remove c-style and python-style comments for each file in the
   directory.
            Search files on the google.
 query
Usage: docsim check-dir [OPTIONS] DIR
 Find most similar pairs for each file in the directory.
Options:
  --plot / --no-plot Draw plot of the lcs occurance distribution
Usage: docsim check-files [OPTIONS] FILENAME1 FILENAME2
 Check the similarity of two code files.
Options:
 --plot / --no-plot Draw plot of the lcs occurance distribution
Usage: docsim query [OPTIONS]
 Search files on the google.
Options:
 -f, --file PATH
-d, --dir TEXT
                   File path
                   Directory of code files
 -n, --num INTEGER
                   Number websites will check on Google
 -k, --keywords TEXT Keywords for searching on google
 -w, --website TEXT
                   Website to search on google, default value:
                   www.geeksforgeeks.org
 --plot / --no-plot
                   Darw plot of the lcs occurance distribution of two top
                   documents
```

For implementation Click package is used. The code is shown in the Listing 7.

```
#! /home/mehran/.virtualenvs/lcs/bin/python3
   import click
import os
2
  import sys
  import re
5
   from scraping import google_lcs
  from docs_sim import Docs_Sim
